INTRADAY STOCK MARKET DATA ANALYSIS: BASED ON SIMULATION AND EMPIRICAL STUDIES

Lokesh Kumar Shrivastav
Computer Science & Engineering, AMITY UNIVERSITY
Noida, Uttar Pradesh – 201303, India

Abstract - The effect of periodic time dependence in interest rate of stock price movement is investigated. The model is based on Black – Schloes SDE time – dependent rate, whole solution is governed by lognormal process. The striking price is modeled as FPT and its behavior is analyzed by carrying out extensive Monte Carlo simulation of SDE. A new phenomenon of damped oscillatory behavior of FTP is predicted.

I. INTRODUCTION

The understanding of the stochastic dynamics of stock price is a challenging problem. During the past decades many sophisticated mathematical and computational techniques have been developed for analyzing financial markets. Many aspects related to this problem cannot be solved analytically and one has to resort to extensive simulation studies. This gave the birth of a new field called as computational finance, which requires development of computational algorithms. The solution of PDE and Monte-Carlo simulation enable us to study different aspects of financial derivatives and analysis of portfolio risks [1-5]. Monte Carlo Method is a simulation technique, which makes use of random numbers. These numbers are independent and identically uniformly distributed. Earlier data was neither helping to predict the price of the stock in future nor explored the dynamics of stock price. Computational finance models attempt to capture the randomness of a stock's price moment in future. In a fixed future time, the change in stock's price is modeled as a random variable having a normal distribution. The standard deviation of the normal variation depends on the time duration as well as the volatility of the market. When the market becomes more volatile then we look further ahead, this mean, the less likely the stock will have a price near the adjusted current price [2].

The Intraday Trend Behavior of Different Stocks

The Intraday Probability Distribution Stocks

It has been found that the price of stock *S (t)* is Lognormal distributed. So *S(t)* takes value in (0, ∞). The probability density function of S (t) is given by:

$$P(S \mid S_0, t) = \frac{e^{-\left(\frac{\log(S/S_0)-(\mu-\sigma^2/2)t}{2\sigma^2 t}\right)^2}}{S\sigma\sqrt{2\pi t}}$$, for s>0,

Where, μ – mean parameter and σ – volatility (fluctuation about mean parameter)
The expected value, second moment and variance of S (t) are given by:

$$E(S(t)) = S_0 e^{\mu t}$$
$$E(S(t)^2) = S_0^2 e^{(2\mu+\sigma 2)t}$$
$$\sigma^2(t) = \text{var}(S(t)) = S_0^2 e^{2\mu t}(e^{\sigma 2t} - 1)$$

The estimated parameters and its corresponding standard errors

μ =	4.87023	0.000210841
σ =	0.133275	0.000149087

The estimated value of μ and σ along with their estimation errors are given by Parameter Estimate Std. Err.

μ = 4.73203 0.000206708

σ = 0.130663 0.000146165

The Intraday Probability Distribution Stock Returns

The stock returns can be defined as:

$$R(t) = \log\left(\frac{S_t}{S_{t-1}}\right)$$

The normalized stock returns can be calculated as:

$$r(t) = R(t) - \text{Mean}(R(t))/\text{std}(R(t))$$

It has been observed that the stock returns can be characterized by Gaussian distribution. The Gaussian distribution is defined as

$$F(r,\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(r-\mu)^2}{2\sigma^2}}$$

Where μ is the mean of the distribution and σ is the standard deviation of the distribution.

The intraday Volatility Analysis of Different Stocks

The volatility of stock returns can be calculated as:

Volatility = |Stock returns| = |R(t)|

Applying log – likelihood estimates techniques, we have estimated the parameters μ & σ from the corresponding empirical data.
The estimated value of μ & σ are as given below

Parameter	Estimate	Std. Err.
μ =	-3.29818	9.84077e-06
σ =	0.00622046	6.95849e-06

II. AIM AND SCOPE OF ANALYSIS

The interesting find out in this chapter after it has been analyzed from the three empirical data sets, that the price fluctuation of stock and its volatility distribution are well captured by lognormal distribution. But stock returns distributions are not characterized by the well–known Gaussian distribution. So there is deep underlying mechanism is needed to analyze the non – Gaussian behavior of Intra day high frequency stock returns.

ABOUT IJEAST

International journal of Engineering Applied Science and Technology (IJEAST) is a peer-reviewed, open access journal that publishes high - quality research paper in the field of Engineering, Applied Science and Technology.

IJEAST aims to provide a platform for researchers, academicians, and professionals to share their innovative ideas, research findings, and practical experiences with the global scientific community.

JOURNAL METRICS

H-INDEX	i10-INDEX	IJEAST CITATIONS	PEER-REVIEWED & OPEN ACCESS
33	154	9,647 (IJEAST CITATIONS)	PUBLISHED MONTHLY

PEER REVIEWED

All submission are rigorously peer reviewed to ensure quality.

AUTHORS ARE OUR PRIORITY

We value our authors and recognize their contribution to the advancement of research and knowledge.

OPEN ACCESS

Free and unrestricted access to research for all.

GLOBAL REACH

Connecting researchers and professionals worldwide.

TIMELY PUBLICATION

We ensure a swift and efficient publication process.
