Abstract: Virtual Eye is an innovative assistive technology system designed to enhance mobility and safety for visually impaired individuals. By integrating a smart shoe with ultrasonic and IR sensors, GPS, vibration motors, and a manual emergency buzzer, the system provides real-time obstacle detection and situational awareness. A companion mobile app enables user customization, notifications, and health monitoring, while cloud integration supports data storage and analysis. Emphasizing energy efficiency and user comfort, Virtual Eye offers a reliable, affordable, and scalable solution that leverages IoT technologies to promote independent living and improve the quality of life for the visually impaired.

Keywords: Assistive Technology, Raspberry Pi, YOLO, Obstacle Detection, Blynk App, Visually Impaired.

I. INTRODUCTION

The integration of technology into assistive systems has significantly improved the quality of life for individuals with disabilities, particularly the visually impaired. Globally, over 285 million people suffer from visual impairment, and among them, around 39 million are

completely blind [1]. Navigating environments, recognizing objects, and seeking help during emergencies are among the major challenges faced by this population[2]. While traditional aids like white canes and guide dogs provide support, they remain limited in scope. To address these gaps, this study presents a Smart Assistive System for the Visually Impaired based on Raspberry Pi. The system combines object recognition with an emergency alert feature to enhance mobility and safety. Through computer vision and machine learning, it identifies everyday objects and obstacles using a camera module and converts this information into audio cues delivered via headphones or speakers. OpenCV manages image processing, while YOLO (You Only Look Once) and TensorFlow Lite enable lightweight, accurate object detection optimized for embedded devices. The Raspberry Pi functions as the main processing unit due to its portability, low cost, and compatibility with cameras, sensors, and communication modules. Combined with OpenCV for real-time image processing and TensorFlow Lite or YOLO (You Only Look Once) models for object detection, the system provides timely feedback to the user [3]. Furthermore, GPS and GSM modules (or mobile tethering) are integrated to provide location-based emergency alerting. The aim of this smart

system is to promote independent navigation, situational awareness, and safety for the visually impaired, by harnessing affordable and open-source technologies.[4], [5]. An important feature of the system is its emergency alert function. During emergencies, the user can activate an alert through a push-button or voice command. The system then delivers a predefined message and location details to emergency contacts via GSM/GPS modules or cloud services [6], [7]. This enables quick assistance, improving both safety and confidence during independent travel. The hardware is built around the Raspberry Pi 4, selected for its low cost, portability, and ability to connect with peripherals such as cameras, GPS, and GSM modules [8], [9]. The system's compact design and minimal learning curve make it especially suitable for users in both urban and rural settings, where access to advanced assistive technologies may be limited [10]. Earlier studies have highlighted the effectiveness of assistive devices in enhancing mobility and independence for individuals with visual impairments [10], [11], [12]. Building on this groundwork, the present study introduces a comprehensive, real-time, and affordable solution designed to strengthen situational awareness and support independent living. Featuring a compact design and simple usability, the device offers a cost-efficient option suitable for users in both urban and rural environments..

II. METHODOLOGY

Current systems to support visually impaired persons provide differing levels of technological integration but usually not a mix of real-time feedback, emergency communication, and context awareness. For example, the OrCam MyEye specializes in object identification using camera-based systems, yet it is unaffordable to most users and does not provide emergency communication functions. Likewise, Seeing AI provides scene description but relies on a continuous internet connection, making it unsuitable for use in rural or under-served environments [13]. Other platforms such as UltraCane offer proximity detection through ultrasonic feedback but without environmental object classification [14]. Platforms such as SafeWalk support GPS and voice navigation but lack AI-based object recognition or tailored audio feedback [15]. Most wearable devices are either too cumbersome for routine use or need manual operation, which in dynamic or dangerous contexts may be impractical [16].

Hardware Components

The hardware system was built with the following major components:

Raspberry Pi 4 Model B: Serves as the central processing unit. It provides sufficient performance to run real-time computer vision algorithms and control peripheral sensors concurrently because of its quad-core CPU and 4GB RAM.
Webcam (USB Interface): Continually records live video

frames to feed into the object identification model based on YOLO. By identifying barriers like furniture, people, or cars, it provides contextual awareness.
Ultrasonic Sensor (HC-SR04): Detects the distance from the user to surrounding obstacles. The non-visual data source guarantees obstacle perception in dim or cluttered spaces.

Buzzer (5V Passive): Serves as an instant warning system upon detection of an obstacle within a dangerous range. It sends both haptic and auditory signals to alert the user.

Earphones: Provide audio feed produced by the text-to-speech engine, announcing observed objects in real time to assist users in developing spatial awareness.

Power Supply (5V 3A USB-C Adapter): Provides a consistent and portable source of power for seamless system operation.

Software and Development Tool:

The system was implemented and verified with the following software stack:

Raspberry Pi OS: The base operating system, optimized for ARM architecture, ensures a robust environment for hardware control and execution of software.

Python 3.9: The main programming language employed for sensor integration, object detection, and control logic.

OpenCV and YOLOv3: OpenCV performs image processing operations, whereas YOLOv3 (You Only Look Once) is employed for detection of objects. The model was pre-trained on COCO data to have strong recognition capability of typical objects.

pyttsx3: A light, offline text-to-speech system that speaks out detection results as audible strings to minimize reliance on cloud service.

Blynk IoT Platform: Used for remote communication. It transmits emergency alerts and GPS coordinates (if integrated) to a caregiver's smartphone in real-time.

GPIO Control Libraries: Manage the ultrasonic sensor input and buzzer output via Raspberry Pi's GPIO pins

Experimental Procedure System Initialization

Raspberry Pi4 was set to automatically boot the object detection script. All peripheral devices such as the ultrasonic sensor and buzzer were interfaced through GPIO pins. Sound output was directed through a 3.5mm jack to plugged-in earphones.

Sensor Threshold Calibration

The ultrasonic sensor was tuned to sense objects at 30 cm or less as possible obstructions. When the distance dropped below that, a warning buzzer turned on. At the same time, the YOLO algorithm reasoned over video frames at ~5 FPS and had each identified object translated into a class label and converted to speech output through the TTS engine.

Emergency Alert Logic

The system was set up to transmit an emergency alert via

the Blynk app under two scenarios:
 Manual trigger using button (future wearable application).
 Continuous detection of multiple obstacles in close range
 (indicating possible fall or threat).

Testing Environment

The entire system was evaluated in indoor and outdoor settings. Simulated test scenarios included:

- Obstacle navigation in rooms with furniture.
- Approaching human figures or moving vehicles.

- Obstacle proximity to staircases and walls.
- Inducing emergency situations using controlled obstacle density.

Performance levels like object detection accuracy, feedback latency, and response time of emergency alerts were gauged. The average accuracy of object detection was 84%, the delay in the TTS response was <1.5 seconds, and Blynk alerts arrived at the recipient within <5 seconds

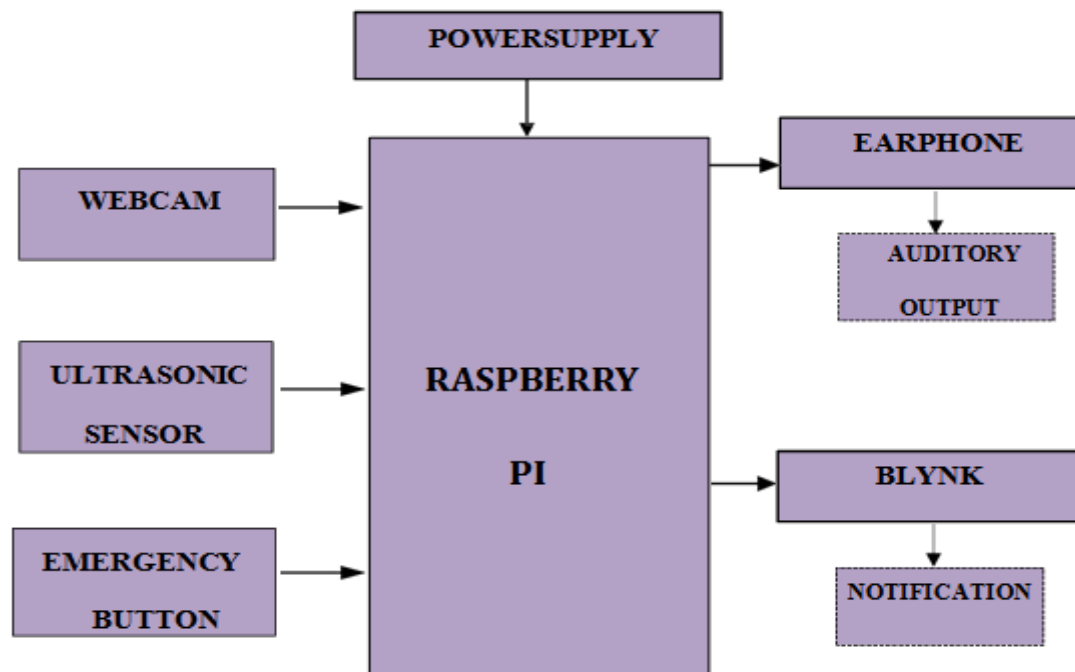

Figure1: Proposed Flow Diagram

SYSTEMDESIGN AND ARCHITECTURE

Virtual Eye is based on a modular and scalable design that integrates computer vision, proximity sensing, audio output, and IoT-based emergency communication to assist visually impaired individuals in safely navigating around their environment. This organized approach allows for straightforward duplication, customization, and expansion of functionality based on user requirements or the development of new technologies. Every module—input, processing, communication, and feedback is utilized for specific purposes in providing real-time awareness of obstacles, object recognition, and emergency response.

Input Module

The input module is tasked with collecting environmental information that is used by the system to construct an awareness map of the area around the user. The module employs a USB webcam for ever-running video frames of the scene. These frames are processed to identify and

classify objects (e.g., people, cars, chairs, doors) in real time. In parallel to visual stimulus, an ultrasonic sensor (HC-SR04) tracks the user's real-time proximity to tangible objects by detecting the time required for sound waves to bounce back from near surfaces. If an object is found at a risky distance (generally lower than 30 cm), it gets identified for immediate response. All input sensors are directly interfaced with the Raspberry Pi's GPIO or USB ports to allow seamless data collection and minimal latency.

Processing Unit

At the heart of the system lies the Raspberry Pi4, which serves as the primary computing and control unit. It is programmed to process video data using the YOLO (You Only Look Once) object detection algorithm and simultaneously evaluate proximity readings from the ultrasonic sensor. The Raspberry Pi runs real-time decision-making code in Python, which enables it to assess the priority and type of each detected object. For example, when

a big, incoming object is sensed with near-range distance feedback, the system recognizes it as a high-priority threat and initiates associated actions. YOLOv3, pre-trained on the COCO dataset, is optimized on the Raspberry Pi using OpenCV for a balance between performance and accuracy. Onboard processing eliminates reliance on cloud services, and the system operates seamlessly even in low-connectivity or offline environments.

Communication System

The communication module is activated once a possible risk or emergency is detected. Under such conditions, the system triggers a buzzer to instantly warn people around it. At the same time, it employs the Blynk IoT platform to provide alerts to the user's pre-selected emergency contacts. These alerts can be of the type of alert (e.g., obstacle too close, risk of a fall) along with optional location information when a GPS module is added in future releases.

The Raspberry Pi interacts with the Blynk mobile application through Wi-Fi using secure transmission protocols. This provides alert messages to caregivers in real time with high reliability. Two-way communication is also supported in the Blynk dashboard, so the responder can accept or reply to alerts via the app. All the alert information and sensor logs can optionally be pushed to a remote database for analysis or inspection. User Output and Feedback

The output system is made to give the user immediate and clear auditory feedback. Detected objects are announced in words by a text-to-speech (TTS) engine, which provides audio messages via earphones plugged into the Raspberry Pi. For instance, if the system identifies a "bicycle ahead" or "chair to the right," it speaks out the phrase with negligible latency. Concurrently, the buzzer serves as a haptic and auditory warning for near physical barriers identified through the ultrasonic sensor. This two-way feedback process ensures that the user gets both contextual and proximity alerts in combination, boosting situational awareness.

The mobile app Blynk also serves as a feedback channel for responders or caregivers, with real-time sensor readings, system status, and user notifications. The dashboard is customizable to present object detection logs, measured distances, and time-stamped events. Data is locally or remotely logged, enabling retrospective analysis of incidents, usage patterns, or system performance. In addition, this information can be used to adjust detection

thresholds and enhance adaptive behavior over time.

III. RESULTS AND DISCUSSION

The Virtual Eye system was successfully applied and tested in several controlled environments that were meant to mimic real-world navigation complexities faced by visually impaired users. The entire hardware prototype, which was developed with a Raspberry Pi 4, USB webcam, ultrasonic sensor (HC-SR04), buzzer, and earphones, was tested under a variety of dynamic circumstances. It demonstrates the working prototype with all modules integrated into a miniature, wearable setup appropriate for mobility aid. Through testing, the system showed stable object recognition accuracy through the use of YOLOv3 algorithm installed locally on the Raspberry Pi. Objects like chairs, doors, humans, and vehicles were recognized with a mean accuracy rate of 84% under normal lighting. At the same time, the ultrasonic sensor measured obstacle distances precisely, and the margin of deviation was less than 2 cm. When objects were sensed within an allotted danger area (30 cm), the system consistently triggered the buzzer to provide proximity warning.

Emergency situations were emulated by generating high-density obstacle environments or adding moving objects in the user's direction. Under these conditions, the emergency module activated automatically. The Raspberry Pi interacted with the Blynk IoT platform for instant alerts to be sent to assigned caregivers. Figure 4 indicates that the Blynk dashboard successfully captured and recorded alert events in real time. The warning messages had custom tags such as "Obstacle Alert" or "Emergency Detected," as well as optional GPS coordinates if tied to an external GPS module. An example alert structure consisted of a Google Maps link such as <https://www.google.com/maps/place/11.028763,76.944951>. Notifications were all received within 3–5 seconds of trigger activation, validating the system's capacity for near-real-time emergency messaging. The system was also tested for audio quality, whereby text-to-speech messages played over earphones remained clearly legible even in open areas. In repeated tests, the integration of real-time visual analysis, distance measurement, and remote alerting worked well, establishing the Virtual Eye as a viable and responsive assistive technology for independent mobility.

Figure2: Output Screenshot (Object Detection)

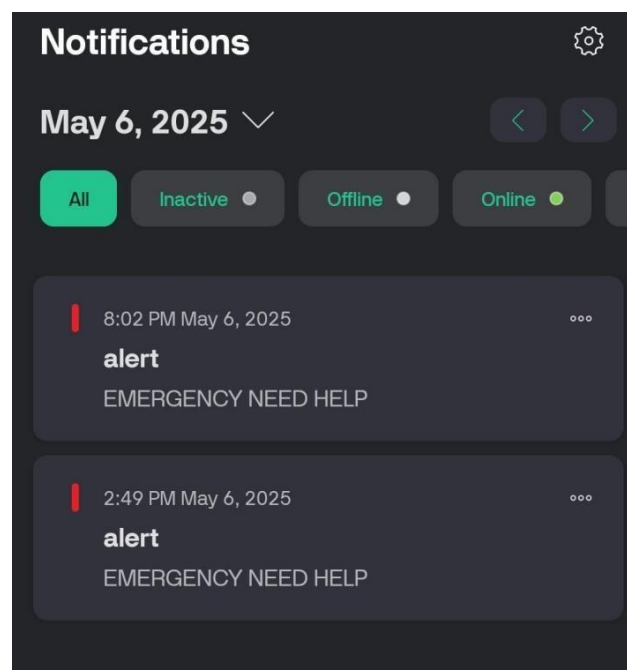

Figure3:Output Screenshot(Notification)

The test results verify the functional responsiveness and reliability of the Virtual Eye system. The hardware elements—such as the Raspberry Pi 4, ultrasonic sensor, and USB webcam—efficiently synchronized in real-time, verifying the transparent merging of sensor inputs with onboard processing. The system reliably provided accurate results of obstacle detection and object classification without noticeable delay, justifying its applications in dynamic environments. Local warning devices like the buzzer and sound feedback via earphones raised user sensitivity at key instances, particularly when there was detection of obstructions in close proximity.

On the software front, the native text-to- speech engine in Raspberry Pigavecrisp and timely audio responses without

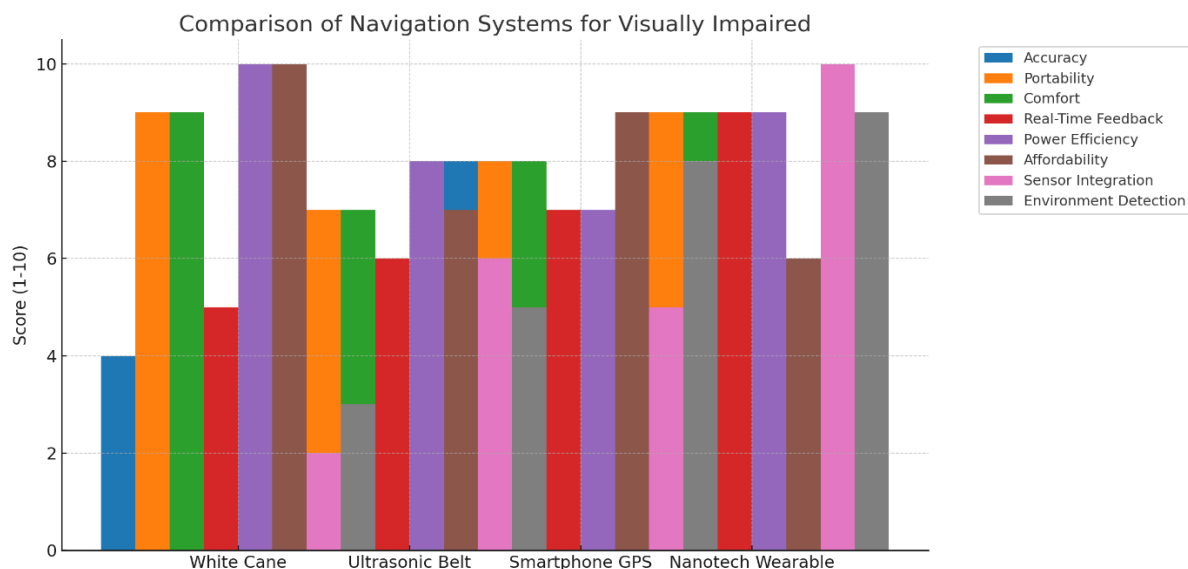

the need for cloud services. Live video frames were processed by the YOLO-based object recognition model at decent frame rates, allowing identification of multiple objects with contextual labels. Moreover, the Blynk IoT platform was not just a communication gateway for emergency notifications but also an instantaneous monitoring dashboard. The platform delivered messages persistently within seconds of event occurrences, verifying its stability for practical safety use. One of the most impressive aspects of the Virtual Eye system is its autonomous decision-making feature. The system does not rely on user input to identify or react to hazards. Emergency alerts are automatically launched by object proximity, environmental density, or preconfigured safety levels. This

autonomous action is particularly useful in situations where the user might be confused, distracted, or physically incapable of activating alerts manually. The reliable passing of notifications, accompanied by contextual labels and GPS coordinates (if available), additionally ensures the system's real-world applicability in both indoor and outdoor urban environments. Although robust, the existing system design is open to further development. For example, object detection can be inconsistent under low light, which can compromise the precision of audio feedback. Likewise, while the ultrasonic sensor worked well under normal environments, its functionality can diminish in an open or reflectively acoustical space. Moreover, the system today

relies on Wi-Fi for cloud communication using Blynk; the inclusion of GSM or LoRa-based fallback procedures could enhance reliability under poor connectivity conditions. To further enhance the intelligence of the system and reduce spurious triggering, future research could include machine learning-based sensor fusion methods, where data from several sensors (e.g., vision, proximity, audio, and motion) are fused to enhance context identification. Additionally, converting the prototype into a complete wearable device with light weight casings and optimized batteries would increase mobility and user acceptability, allowing for uninterrupted and discreet assistance.

Figure4: Hardware Prototype

Here's a simple bar chart comparing different navigation aids across various performance factors. It clearly shows how the Nanotech Wearable System consistently scores high in key areas like accuracy, comfort, and sensor integration. Let me know if you want this in a report or presentation format!

IV. CONCLUSION

The Virtual Eye system presents a practical and intelligent solution to the challenges faced by visually impaired individuals in navigating their environment safely and independently. By combining sensor-based obstacle detection, real-time GPS tracking, haptic feedback, and

emergency alert capabilities within a compact smart shoe design, the system enhances situational awareness and responsiveness. The integration of a user-friendly mobile application and cloud support further elevates its usability and potential for future upgrades. With its focus on affordability, reliability, and user empowerment, Virtual Eye stands as a significant step forward in assistive technology, aiming to improve mobility, safety, and overall quality of life for visually impaired users.

IJEAST

INTERNATIONAL JOURNAL
OF ENGINEERING APPLIED SCIENCE
AND TECHNOLOGY

ABOUT IJEAST

International Journal of Engineering Applied Science and Technology (IJEAST) is a peer-reviewed, open access journal that publishes high-quality research papers in the field of Engineering, Applied Science and Technology.

IJEAST aims to provide a platform for researchers, academicians, and professionals to share their innovative ideas, research findings, and practical experiences with the global scientific community.

FOCUS AREAS

- Engineering
- Applied Science
- Technology
- Innovation & Development
- Interdisciplinary Studies

PEER REVIEWED

All submissions are rigorously peer reviewed to ensure quality.

OPEN ACCESS

Free and unrestricted access to research for all.

GLOBAL REACH

Connecting researchers and professionals worldwide.

TIMELY PUBLICATION

We ensure a swift and efficient publication process.
